A Diverse State

The Salmon River Valley generally divides the moister mixed conifer forests of the Panhandle region from the drier forests of southern Idaho. Much of southern Idaho is rangeland with scattered juniper-dominated woodlands typical of the Great Basin. The highest mountain peaks also occur in southern Idaho. Most of the commercial forest land is found in the north, and Douglas-fir, grand fir, western larch and western redcedar are valuable timber species.
Idaho’s forests are important for many reasons. Forests are home to wildlife, provide watersheds for drinking water, and protect streams that are habitat for many species of fish, including salmon and steelhead. Forests are also important for recreation, and Idaho has over 4.5 million acres of wilderness. Idaho’s forests are renewable, and are an important resource for the forest products industry. Maintaining healthy forests is crucial to protect all the things that they provide.

Forest Ownership in Idaho
The majority of forest land in Idaho is owned by the Federal government (> 16 million acres), and of this, most is administered by the U.S. Forest Service. The state of Idaho owns just under 1.3 million acres, and private landowners own an additional 2.8 million acres. The various owners often have different management objectives.

Idaho’s National Forests
Idaho’s National Forests lie within two administrative regions. The Northern Region (Region 1) is located north of the Salmon River and is comprised of the Idaho Panhandle, Clearwater, Nez Perce and Bitterroot National Forests. The Intermountain Region (Region 4) is in southern Idaho and includes the Boise, Payette, Sawtooth, Salmon, Challis, Targhee and Caribou National Forests.

Idaho’s Forest Industry
Idaho has a productive forest industry, with 2015 revenues of wood and paper products totaling over $2.7 billion. An estimated 11,980 people were directly employed in the forest products industry in 2015, and an additional 13,700 people are employed in associated occupations. Average worker earnings were $56,600 per job, which is nearly 40% higher than the Idaho average. Most of Idaho’s commercial forestland and larger production facilities are located north of the Salmon River. Forest products from Idaho’s forests are sold throughout the world. Aerial Detection Survey Results

**Bark Beetles**

In 2015, mountain pine beetle caused mortality decreased to 158,000 acres. Most of the mortality was in lodgepole pine, but approximately 3,400 acres of ponderosa pine were affected in 2015, an increase from 6,600 acres in 2014. Throughout Idaho, lodgepole pine stands are of an age and size that make them very susceptible to attack. Douglas-fir beetle caused mortality on over 23,000 acres in 2015 compared to approximately 19,000 acres in 2014. Other bark beetle species such as the fir engraver, western pine beetle and pine engraver continue to cause mortality statewide at levels similar to last year.

**Defoliators**

Western spruce budworm is a major defoliator of Douglas-fir and grand fir in Idaho. Approximately 1.1 million acres were affected in 2015 compared to over 529,000 acres in 2014. Most of the defoliation is in southern Idaho. Much of this increase can be attributed to drought. Douglas-fir tussock moth populations increased in southern Idaho in 2015, and limited defoliation may occur in the Sawtooth and Payette National Forests in 2016. No defoliation is expected in northern Idaho in 2016.

**Other Agents**

Drier spring weather in 2015 contributed to a decrease in needle diseases on conifers. Approximately 3,000 acres were affected, compared to over 5,000 acres in 2014. Mortality of subalpine fir, attributed to balsam woolly adelgid, western balsam bark beetle and possible root disease remained similar to 2014 at approximately 25,000 acres.

Notes on Aerial Detection Surveys

A total of 27.2 million acres were surveyed in Idaho in 2015, compared to 25.4 million acres in 2014. It is important to remember that trees attacked by bark beetles do not usually change color until the following year, so mortality observed in 2015 actually represents trees that were attacked in 2014.

Idaho's forests are also significantly impacted by diseases, but not all diseases are easily detected from the air. With the exception of foliar diseases, most forest diseases are not well represented by aerial detection surveys. Root diseases are very common in northern Idaho, affecting over 8 million acres, with most mortality occurring in Douglas-fir, grand fir, and subalpine fir in northern Idaho. Dwarf mistletoes infect over 2.5 million acres of forest statewide. These parasites are especially damaging on western larch, Douglas-fir, lodgepole pine and ponderosa pine. White pine blister rust is widespread throughout the range of western white, whitebark and limber pines, affecting millions of trees, though an acreage estimate would be difficult to determine.
Western spruce budworm infested acres increased in 2015 to approximately 1.1 million acres, compared to over 529,000 acres in 2014. In 2011 the total was over 1.8 million acres. Drought conditions throughout Idaho may have contributed to this increase. Link to USFS publication.

Mountain pine beetle continues to kill susceptible lodgepole, whitebark, and limber pines across the state. Many stands are of a susceptible size, age and density that are favorable for bark beetle attack. Overall the acreage of pines killed has decreased over the last several years. In 2015, the acreage of lodgepole pine damaged was over 151,000 acres compared to more than 278,000 acres in 2014. In some areas, the decrease is due to host depletion. Mountain pine beetle is causing the most mortality in ponderosa pine in Idaho County. The acreage of impacted ponderosa pine decreased somewhat to approximately 3,400 acres. In 2014, just over 6,600 acres of mortality was mapped. Link to USFS publication.

The Douglas-fir tussock moth is a defoliating insect that periodically infests Douglas-fir and true firs in Idaho. Outbreaks occur approximately once per decade, and the most damaging infestations have occurred in northern Idaho. Historically, outbreaks have lasted 1-4 years, and then natural controls bring the populations down to undetectable levels. Populations are increasing in southern Idaho, and may defoliate parts of the Payette and Sawtooth NF’s in 2016. The Douglas-fir tussock moth will probably begin to defoliate forested areas in northern Idaho within the next 5-7 years. Link to USFS brochure.

Gypsy moth survey. Over 3,900 pheromone traps were deployed in Idaho in 2015, with three European gypsy moth captured near Kellogg, in Shoshone County. A delimit survey is planned in this area in 2016. Link to IDL 2015 Gypsy Moth Report.
Key Forest Disease Issues in Idaho

**Root diseases** north of the Salmon River kill millions of trees every year. Douglas-fir and grand fir are particularly susceptible. Root diseases are more prevalent than aerial detection survey data indicate, and are very common in northern Idaho. Root diseases can be managed through silviculture by encouraging tolerant species. While all conifer species are susceptible to root diseases (especially at a young age), pines, western larch and western redcedar are more tolerant, especially after the trees reach 20-25 years of age. *Photo (R) by J. Schwandt USFS.* [Link to additional information](#).

**White pine blister rust** is an introduced disease that kills 5-needled pines (western white, whitebark and limber) throughout western North America. Western white pine (WWP) was the dominant tree species in much of northern Idaho. Due to rust, fire suppression and past management practices, western white pine is now a minor component of many of these same forests. Idaho’s forest type that was dominated by western white pine is now reduced to 5% of its historic levels. The Idaho Department of Lands aggressively plants rust resistant WWP in stands where it was historically present. Western white pine is fast growing, drought tolerant, and is not highly susceptible to root diseases. *Photo (R) by J. Schwandt* [Link to USFS publication](#).

**Dwarf mistletoes** infect many species of conifers in Idaho. Most damage is on western larch, Douglas-fir, ponderosa and lodgepole pines. These parasitic plants reduce growth and over time can kill trees. Dwarf mistletoes are fairly host specific, and can be managed through silviculture by removing heavily infected trees and by converting stands to nonhosts. [Link to USFS publication](#).

**Foliar Diseases** can infect many species of conifers in Idaho, but damage is most noticeable on western larch and lodgepole pine. While the appearance can be dramatic, the effect on trees is usually minor. Cool, wet spring weather during needle development is favorable for disease development. Approximately 600 acres of needle diseases were mapped in 2015, compared to approximately 900 acres in 2014. In 20013, over 16,000 acres were recorded. Drier spring weather in 2014 and 2015 is responsible for this decline. [Link to IDL Forester Forum](#).
Fire Activity in Idaho, 2015

The total acreage burned in Idaho in 2015 was over 804,000 acres, compared to approximately 189,000 acres in 2014. The two largest fires were in USFS Region 4, south of the Salmon River. The Soda and Tepee Springs fires were over 285,000 and 95,000 acres respectively. The Clearwater Valley was severely impacted in 2015, with several fire complexes starting during a lightning storm in August. Burned acreage on lands within the Idaho Department of Lands Protection Area (IDL, Clearwater-Potlatch Timber Protective Association, and Southern Idaho Timber Protective Association) was almost 6 times higher than the 33 year average.
